1. Introduction

Shangri-La Hotel in Colombo is a Five-star luxury hotel located in Colombo, Sri Lanka, providing accommodation, dining, events, and other services to its guests. The hotel operates through several departments such as front office, housekeeping, food and beverage, maintenance, and administration, with each department handling different types of information and daily activities.

With a large number of guests, rooms, employees, suppliers, bookings, and services to manage, handling all this information efficiently can be challenging. Important details such as guest reservations, room availability, billing, employee records, supplier information, and event bookings need to be properly maintained and updated.

When information is handled through separate systems or manual records, it can lead to problems such as incorrect room availability, difficulties in tracking bookings and payments, and delays in accessing important information. Therefore, this project proposes a Hotel Management System that can organize these different areas within a centralized database and make the information easier to manage and retrieve.

2. Objectives

The main objective of the proposed database is to create a centralized system for managing the main operational information of Shangri-La Hotel Colombo. The system will reduce the need for manual and separate record-keeping and make important information easier to store, update, and retrieve.

The database will help improve the management of room availability and reservations while maintaining accurate guest billing and payment records. It will also keep employee and department information in a structured manner and allow housekeeping and other service tasks to be recorded and assigned.

Another objective is to manage supplier information and hotel inventory, as well as maintain records of event and conference bookings. The system will also support SQL queries and reports to provide useful information about the hotel's operations and assist with day-to-day decision-making. In addition, suitable user roles and permissions will be used to control access to the database and protect the information stored in the system.

3. Scope of the Project

The proposed Hotel Management System will cover the main day-to-day operations of a hotel. It will manage guest registration and profile details, room categories, room availability, reservations, and the check-in and check-out process. The system will also handle billing and payment records, including any outstanding balances for guests.

Employee and department details will be maintained within the system, while housekeeping activities can be recorded and assigned to employees. Room service requests made by guests will also be recorded so that the hotel can keep track of the services requested.

The system will include restaurant management, where restaurant tables and customer orders can be recorded. Supplier details and hotel inventory will also be managed to keep track of supplies used by the hotel. In addition, the system will support event and conference bookings by storing the relevant booking details.

Guest feedback will also be recorded and maintained for future reference. Finally, SQL queries will be used to generate useful information from the database, such as room occupancy status, pending reservations, billing summaries, employee task loads, inventory information, and popular dining items.
